

A319929(n, k) can be discovered and motivated as follows.

Ask: When is $f(a, b) = xa + yb + z$ associative?

$$f(f(a, b), c) = f(a, f(b, c))$$

$$f(xa+yb+z, c) = f(a, xb+yc+z)$$

$$x(xa+yb+z) + yc + z = xa + y(xb+yc+z) + z$$

$$x^2a + xyb + xz + yc + z = xa + xyb + y^2c + yz + z$$

$$(x^2 - x)a - (y^2 - y)c + (x - y)z = 0$$

Since the a term, the c term and the constant term are independent, all three components must equal 0.

$$(1) x^2 - x = 0 \text{ and}$$

$$(2) y^2 - y = 0 \text{ and}$$

$$(3) (x - y)z = 0$$

$$(1) x = 1 \text{ or } x = 0$$

$$(2) y = 1 \text{ or } y = 0$$

$$(3) x = y \text{ or } z = 0$$

Case 1: choose $x=1$ and $y=1$, then z is unrestricted

Case 2: choose $x=1$ and $y=0$, then z is 0

Case 3: choose $x=0$ and $y=1$, then z is 0

Case 4: choose $x=0$ and $y=0$, then z is unrestricted

We've learned that $f(a, b)$ is associative if and only if

$$f(a, b) = a + b + z \quad \text{for any } z$$

$$\text{or } f(a, b) = a$$

$$\text{or } f(a, b) = b$$

$$\text{or } f(a, b) = z \quad \text{for any } z$$

There is no reason a , b and z cannot be complex numbers.

The last three functions are trivial examples of associativity. $f(a, b) = a + b + z$ is addition with an offset. Its identity element is $-z$.

Now, there is another way to interpret the result of this investigation into simple associative arithmetic. We can come away with a single function that is split into four cases.

$$f(a, b) = \begin{cases} a + b + z_1 & \text{if } a \text{ and } b \text{ are in class } z_1 \\ a & \text{if } a \text{ is in class } z_2 \text{ and } b \text{ is in class } z_1 \\ b & \text{if } a \text{ is in class } z_1 \text{ and } b \text{ is in class } z_2 \\ z_2 & \text{if } a \text{ and } b \text{ are in class } z_2 \end{cases}$$

We assume the following. The numbers z_1 and z_2 are not equal. The two classes are mutually exclusive and together they include all a and b . There is a suitable rule for adding elements of the two classes and placing the result in one of the classes.

A function of this form is globally associative. It has $-z_1$ for its unique two-sided identity element. z_2 is its unique two-sided zero element, meaning $f(a, z_2) = z_2$ for all a . By itself, $f(a, b) = a + b + z_1$ has an identity element, $-z_1$; $f(a, b) = z_2$ has a zero element, z_2 . For $f(a, b) = a$ by itself, any number can be a left zero element or a right identity element. The situation is reversed for $f(a, b) = b$.

If we restrict a and b to positive integers, use the positive odd numbers and the positive even numbers as the two classes, and choose $z_1 = -1$ and $z_2 = 0$, we get A319929(n, k).
