end

$$k = 1, n < 8192;$$
  $k = 3, n < 1280;$   $k = 5, n < 2005;$   $k = 7, n < 1280.$ 

The calculations were checked by a second run, so that we can say with some assurance that Table 1 is accurate and complete to the stated bounds. Notice that there are no primes of the form  $47 \cdot 2^n + 1$  with n < 512.

The checking of this table was finished in the spring of 1957, except that at this time the case k=5 was complete only for n<1585. In the fall of 1957, the range for k=5 was extended to n<2005. One additional prime was discovered, namely  $5 \cdot 2^{1947} + 1$ . Notice that there is not a single prime of the form  $5 \cdot 2^n + 1$  with 127 < n < 1947. The new prime is the largest in the table by far. It is the fourth largest prime known at present, the larger ones being the Mersenne primes  $2^n - 1$  with n=3217, 2281, and 2203; see Riesel [9] and Robinson [10].

In May 1957, eighteen copies of a table [12] of 312 pages were printed on a tabulator, giving the results of the computation. The table has been sent to a few libraries, and deposited in the Unpublished Mathematical Tables file of the journal Mathematical Tables and Other Aids to Computation. The smallest factor of  $N=k\cdot 2^n+1$  was printed where found. Otherwise, there was printed an indication whether N is prime or composite, and the value of the smallest positive a such that (a/N)=-1, which was used in testing N for primeness. The table is too bulky for publication, but the information of most interest, aside from the factors of Fermat numbers discussed in \$2, is the character of N (prime or composite), and this can be determined from Table 1.

On the other hand, information of some interest, such as the fact that the smallest factor of  $5 \cdot 2^{79} + 1$  is 98801, is necessarily lost in the condensation. Besides the smallest factors, another item eliminated is the smallest nonresidues. In this case, a summary appears to be of interest. The largest value of a which we encountered was a=47. For k<100, this appeared only for two composite values of N, namely  $N=33\cdot 2^{172}+1$  and  $N=69\cdot 2^{365}+1$ . It did appear also for a prime  $N=1575\cdot 2^{147}+1$  which we had occasion to test. If we restrict ourselves to prime values of N with k<100, we have the following empirical result.

THEOREM. If  $N = k \cdot 2^n + 1$  is prime, where k is odd, 0 < k < 100, and 0 < n < 512, then the smallest positive quadratic nonresidue of N does not exceed 23. The smallest nonresidue is 23 in just three cases:

$$N = 39 \cdot 2^{13} + 1$$
,  $33 \cdot 2^{28} + 1$ ,  $57 \cdot 2^{90} + 1$ .

The numbers of the form N=1. They were studied by Cunningha page 22 that for just 47 of these numbers greater than 1000. They give The remaining 44 numbers were only one turned out to be prime, the correctness of the results in [2] Cullen prime with  $2 \le n \le 1000$ .

FACTORS OF FI

We now give a brief survey of  $k \cdot 2^n + 1$  or of factors of numbers of the form  $k \cdot 2^n + 1$  was given by with Table 1 shows that there are ham [1, pp. 56–73], lists a numb none exceeding  $10^8$ , together with chik [5, pp. 12–13], gives the sr =  $k \cdot 2^n + 1$  with k odd, 1 < k < 100, [6, pp. 222–232], the range is ext  $< 10^{12}$ , and a list of primes from the comparison with the table [12] pp. 222–223. The following correct

41	22	5	3
53	29	23	11
57	21	3	5

In the eleven cases where Kraitchil to be a factor also; in the other thromention a table of primes of the fe

2. Factors of Fermat numbers. If a prime, then it was also tested to Fermat number  $F_m = 2^{2^m} + 1$ . This of the last sentence of [10]. Since, for satisfies  $p \equiv 1 \pmod{2^{m+2}}$ , we needed as a factor of  $F_m$  only for  $m \leq n-2$ . Was very similar to that used for testing p = 1.

Besides testing the primes in Tabl the numbers  $k \cdot 2^n + 1$  with k = 119,

1280; k = 5, n < 2005;

1280, k = 3, n < 2003

second run, so that we can say accurate and complete to the no primes of the form  $47 \cdot 2^n + 1$ 

hed in the spring of 1957, except complete only for n < 1585. In was extended to n < 2005. One ely 5.21947+1. Notice that there +1 with 127 < n < 1947. The new ir. It is the fourth largest prime ing the Mersenne primes  $2^n-1$ esel 9 and Robinson [10]. a table [12] of 312 pages were sults of the computation. The and deposited in the Unpubhe journal Mathematical Tables smallest factor of  $N = k \cdot 2^n + 1$ the as printed an indication the value of the smallest posias used in testing N for primeication, but the information of of Fermat numbers discussed in nposite), and this can be deter-

some interest, such as the fact is 98801, is necessarily lost in at factors, another item eliminiscase, a summary appears to a which we encountered was for two composite values of N. 15+1. It did appear also for a occasion to test. If we restrict the <100, we have the following

where k is odd, 0 < k < 100, and wadratic nonresidue of N does 23 in just three cases:

+1,  $57 \cdot 2^{90} + 1$ .

The numbers of the form  $N=n\cdot 2^n+1$  are called Cullen numbers. They were studied by Cunningham and Woodall [2], who stated on page 22 that for just 47 of these numbers with  $n \le 1000$  is the smallest factor greater than 1000. They give a factor in three of these cases. The remaining 44 numbers were tested on the SWAC, and of these only one turned out to be prime, namely  $N=141\cdot 2^{141}+1$ . Assuming the correctness of the results in [2], we can say that this is the only Cullen prime with  $2 \le n \le 1000$ .

We now give a brief survey of earlier tables of primes of the form  $k \cdot 2^n + 1$  or of factors of numbers of this form. A short list of primes of the form  $k \cdot 2^n + 1$  was given by Seelhoff [15] in 1886. A comparison with Table 1 shows that there are several errors in his list. Cunning-ham [1, pp. 56–73], lists a number of primes of the form  $k \cdot 2^n + 1$ , none exceeding  $10^8$ , together with certain quadratic partitions. Kraitchik [5, pp. 12–13], gives the smallest factor of each number  $N = k \cdot 2^n + 1$  with k odd, 1 < k < 100, and  $2 \cdot 10^8 < N < 10^{12}$ . In Kraitchik [6, pp. 222–232], the range is extended to 0 < k < 1000 and  $10^8 < N < 10^{12}$ , and a list of primes from the table appears on pp. 233–235. A comparison with the table [12] disclosed a number of errors on pp. 222–223. The following corrections may be noted.

k	n	FOR	READ	k	n	FOR	READ
13	23	5	3	57	32	442837	73
15	28	263	241	59	33	17	11
25	34	33461	2129	63	29	29	61
31	24	467	311	67	21	5	3
41	22	5	3	69	22	59	53
53	29	23	11	69	23	53	12227
57	21	3	5	71	25	977	13

In the eleven cases where Kraitchik's entry is too large, it turns out to be a factor also; in the other three cases, it cannot be. Finally, we mention a table of primes of the form  $k \cdot 2^n - 1$  given by Riesel [8].

2. Factors of Fermat numbers. If the number N turned out to be prime, then it was also tested to find whether it is a factor of any termat number  $F_m = 2^{2^m} + 1$ . This carries out a project suggested in the last sentence of [10]. Since, for  $m \ge 2$ , every prime factor p of  $F_m$  satisfies  $p \equiv 1 \pmod{2^{m+2}}$ , we needed to try the number  $N = k \cdot 2^n + 1$  a factor of  $F_m$  only for  $m \le n-2$ . The routine for making this test was very similar to that used for testing N for primeness.

Besides testing the primes in Table 1 as factors of Fermat numbers, e numbers  $k \cdot 2^n + 1$  with k = 119, 397, 579, 973, 1071, 1575, 11131,

and 52347, and with n < 256, were also examined. These values of k were chosen because a prime factor of a Fermat number was already known in each case. One additional prime factor was found, corresponding to k = 1575; in fact,  $1575 \cdot 2^{157} + 1$  is a divisor of  $F_{150}$ . This factor, as well as thirteen with k < 100, was given in the preliminary report [11]. The testing of the primes in Table 1 was completed in 1957, and two more factors of Fermat numbers were found, namely

$$95 \cdot 2^{61} + 1 \mid F_{58}, \quad 5 \cdot 2^{1947} + 1 \mid F_{1945},$$

of which the first appears in [12]. Some further experimentation with values of k > 100 was undertaken in 1957 by John L. Selfridge, using a modified form of my routine. Four other factors of Fermat numbers were found, namely

$$425 \cdot 2^{79} + 1 \mid F_{77},$$
  $271 \cdot 2^{84} + 1 \mid F_{81},$   $403 \cdot 2^{252} + 1 \mid F_{250},$   $177 \cdot 2^{271} + 1 \mid F_{267}.$ 

A list of all known prime factors of composite Fermat numbers appears in Table 2, together with the date found or published, and the discoverer. See Dickson [3, Chapter XV], for references on Fermat numbers prior to 1918. Kraitchik's factor for m=15 is mentioned on page 220 of his book [5], and is misquoted on the following page. Selfridge's factors for m=10 and 16 were announced in [16]. In all, there are now 38 prime factors  $k \cdot 2^n + 1$  of 33 different composite Fermat numbers  $F_m$  known. As mentioned earlier, the difference n-m is at least 2; the values of this difference which actually occur in the table are 2, 3, 4, 6, 7, 8.

It should also be recalled that  $F_m$  is prime for  $m=0,\ 1,\ 2,\ 3,\ 4$ . Furthermore, Morehead and Western showed some fifty years ago that  $F_7$  and  $F_8$  are composite, and their calculation was verified in [10], but no factor of either has been found. It was shown in [13] that there are no additional prime factors p of Fermat numbers with  $p<2^{32}$ , and also no additional factors  $p<2^{35}$  such that  $p\equiv 1\pmod{2^{15}}$ . In particular,  $F_7$  is a product of either 2 or 3 prime factors, and  $F_{11}$  has no factor  $p<2^{35}$ . The character of  $F_{13}$  is still unknown.

The condition that a prime  $N = k \cdot 2^n + 1$  divides some Fermat number is exactly that 2 should be a kth power residue mod N. For 2 is a kth power residue mod N if and only if  $2^{(N-1)/k} \equiv 1 \pmod{N}$ , that is,  $2^{2^n} \equiv 1 \pmod{N}$ , and this is equivalent to having  $2^{2^m} \equiv -1 \pmod{N}$ , or  $N \mid F_m$ , for some m < n. This is not usually helpful in deciding whether N is a factor of any Fermat number, but there is one case in which it is, as is shown by the proof of the following theorem, which was given by Morehead [7].

THEOREM. A prime of the form  $N=3\cdot 2^n+1$ , where n is even, cannot be a factor of any Fermat number.

PROOF. The condition that 2 should be a cubic residue mod N, for any prime  $N \equiv 1 \pmod 6$ , is that in the unique representation of N in the form  $N = A^2 + 3B^2$ , the number B should be a multiple of 3. (See, for example, Friedman and Hall [4].) Now, in the present case, A = 1 and  $B = 2^{n/2}$ , so that 2 is not a cubic residue. Hence, as previously noted, N cannot be a factor of any Fermat number.

Actually, the residue of  $2^{2^{n-2}} \pmod{N}$  was computed in this case also, and, curiously enough, this was the only case noticed where the residue had an interesting form without being  $\pm 1$ . It is, in fact, easy to verify that if  $N=3\cdot 2^n+1$  is prime, and n>2 is even, then

$$2^{2^{n-2}} \equiv 3(\pm 2^{n-1} \pm 2^{(n/2)-1}) \pmod{N},$$

with some combination of signs. It may be of interest to record the signs actually obtained. For the eleven even values of n with 2 < n < 1280 for which  $N = 3 \cdot 2^n + 1$  is prime, the signs in the above congruence were as follows:

$$+ + \text{ for } n = 276;$$
  $- + \text{ for } n = 6, 18, 66, 438, 534;$   
 $+ - \text{ for } n = 30;$   $- - \text{ for } n = 8, 12, 36, 408.$ 

The first sign being plus is found to correspond to 2 being a quartic residue mod N. It is not clear why this case should be unusual.

Added in proof. It follows from a recent unpublished result of Emma Lehmer that the two signs will be like if  $n \equiv 0 \pmod{4}$  and unlike if  $n \equiv 2 \pmod{4}$ .
