# THE NUMBER OF BINARY $n \times m$ MATRICES WITH AT MOST $k$ 1'S IN EACH ROW OR COLUMN 

RICHARD J. MATHAR

#### Abstract

We count the the number of binary $(0,1)$-matrices with a given limit $k$ on the number of 1's in each row and each column. The computation is recursive starting from the simplest case of the matrix with a single row.

## 1. SCOPE

Definition 1. Let $A_{n, m, k}$ be the number of (0,1)-matrices with $n$ rows, $m$ columns and no more than $k$ 1's in each of the rows and in each of the columns.
Example 1. The simplest example is

$$
\begin{equation*}
A_{n, m, 0}=1, \tag{1}
\end{equation*}
$$

because allowing no 1's in the matrices means only the matrix with all elements equal to 0 is admitted.

Example 2. The number of binary matrices with a single column and no more than $k$ 1's in that column is

$$
\begin{equation*}
A_{n, 1, k}=\sum_{f=0}^{k}\binom{n}{f} \tag{2}
\end{equation*}
$$

because the $f$ 1's may be freely distributed over the column.
Example 3. If the number of rows and the number of columns are both not larger than $k$, there is effectively no constraint on the placement of 1's:

$$
\begin{equation*}
A_{n, m, k}=2^{n m}, \quad n \leq k \text { and } m \leq k . \tag{3}
\end{equation*}
$$

Summing its matrix elements down columns, each ( 0,1 )-matrix can be categorized by a frequency vector with elements $c_{f}$ counting the number of columns with $f$ 1's, i.e., by the number $c_{0}$ of columns without any 1 , the number $c_{1}$ of columns with one 1 , and so on. The natural constraints for matrices restricted to $k 1$ 's are

$$
\begin{gather*}
\sum_{f=0}^{k} c_{f}=m  \tag{4}\\
0 \leq c_{f} \leq m, \quad \forall f . \tag{5}
\end{gather*}
$$

Definition 2. Let $A_{n, m, k}\left(c_{0}, c_{1}, \ldots c_{k}\right)$ be the number of ( 0,1 )-matrices with $n$ rows, $m$ columns, no more than $k$ 1's in each row and each column, and with exactly $c_{f}$ columns with $f$ 1's.

[^0]Example 4. The $2 \times 3$ matrix

$$
\left(\begin{array}{lll}
0 & 1 & 0  \tag{6}\\
0 & 1 & 0
\end{array}\right)
$$

has two columns without 1, no column with one 1, and one column with two 1's, so $c_{0}=2, c_{1}=0, c_{2}=1$.

Example 5. In a matrix with 1 row

$$
A_{1, m, k}\left(c_{0}, c_{1}, \ldots c_{k}\right)= \begin{cases}\binom{m}{c_{1}}, & c_{1} \leq k \text { and } c_{f}=0 \forall f>1, \text { and } c_{0}+c_{1}=m  \tag{7}\\ 0, & \text { otherwise }\end{cases}
$$

because we allow up to $k$ 1's in that row and may distribute them over the $m$ columns.
Definition 3. Let $C(n, k)$ denote the number of compositions of $n$ into $k$ nonnegative parts.

Remark 1. The number $C(n, k)$ equals the number of compositions of $n+k$ into $k$ positive parts. The Maple program in the Appendix generates the compositions into non-negative parts by (i) calling the function that generates positive parts and (ii) subtracting 1 from each of the parts.

This frequency statistics refines the full count of matrices:

$$
\begin{equation*}
A_{n, m, k}=\sum_{C(m, k+1)=0^{c_{0}} 1^{c_{1} \cdots k^{c_{k}}}} A_{n, m, k}\left(c_{0}, c_{1}, \ldots c_{k}\right) . \tag{8}
\end{equation*}
$$

Example 6. The admitted matrices with $m=4$ columns and up to $k=2$ 1's per column may separately by counted by the compositions $4=4+0+0=3+1+0=$ $2+2+0=1+3+0=\cdots=0+0+4$, i.e. the matrices with 4 columns without 1 's, the matrices with 3 columns without 1's and 1 column with one 1 , the matrices with 2 columns without 1's and 2 columns with one 1 etc and eventually the matrices with 4 columns of two 1 's.

## 2. Recurrence

The number of admitted matrices with $n$ rows is computed by considering the number of admitted matrices with $n-1$ rows and the number of ways of entering a total of up to $k$ 1's in the final row distributed over the number of columns that have not yet exausted the upper limit of $k$ in their count. The recurrence is anchored at Equation (7). We add a total of $N=d_{0}+d_{1}+\cdots+d_{k-1} 1$ 's in the bottom row, $d_{0}$ of these placed at columns that had no 1 's in the previous rows, $d_{1}$ placed at columns that hat one 1 in the previous rows and so on. The lower index of the $d$ is limited to $k-1$ because we cannot insert 1's into columns that have already $k$ 1's in the previous rows:

$$
\begin{align*}
& A_{n, m, k}\left(c_{0}-d_{0}, c_{1}-d_{1}+d_{0}, c_{2}-d_{2}+d_{1}, \ldots, c_{k}+d_{k-1}\right)=  \tag{9}\\
& \sum_{0 \leq N \leq k} \sum_{C(N, k)=0^{d_{0}}} \prod_{1^{d_{1}} \ldots(k-1)^{d_{k-1}}} \prod_{f=0}^{k-1}\binom{c_{f}}{d_{f}} A_{n-1, m, k}\left(c_{0}, c_{1}, \ldots, c_{k}\right) .
\end{align*}
$$

The binomial factors on the right hand side count the number of ways of distributing $d_{f} 1$ 's in row $n$ over the $c_{f}$ columns that still admit additional 1 's. The frequency vector on the left hand side shows that (i) adding $d_{0}$ 1's to columns that had no

1's in the previous rows diminishes the number of columns without 1's by $d_{0}$ and increases the number of columns with one 1 by $d_{0}$, that (ii) adding $d_{1} 1$ 's to columns that had a single 1 in the previous rows diminishes the number of columns with a single 1 by $d_{1}$ and increases the number of columns with two 1 's by $d_{1}$, and so on.

Remark 2. The implementation of (9) in the Maple program in the Appendix works with the reduced variables $c_{0}^{\prime} \equiv c_{0}-d_{0}, c_{f}^{\prime} \equiv c_{f}-d_{f}+d_{f-1}$ where $1 \leq f<k$ and $c_{k}^{\prime}=c_{k}+d_{k-1}$.

## 3. Results

The numbers $A_{n, m, k}$ are collected for $1 \leq k \leq 4$ in tables 1-4. Transposition does not effect the constraints on the maximum number of 1's, so these tables are symmetric $A_{n, m, k}=A_{m, n, k}$ and need only to be shown in the range $1 \leq m \leq n$.

On the diagonal of Table 1 we recognize the $A_{n, n, 1}$ of [1, A002720]. The column $m=1$ in Table 1 is a simple consequence of the fact that allowing a single 1 in a binary $n \times 1$ matrix allows either no one or allows that 1 in any of the $n$ rows, $A_{n, 1,1}=n+1$.

On the diagonal of Table 2 we recognize the $A_{n, n, 2}$ of [1, A197458]. The column $m=1$ in that table shows [1, A000124] according to (2).

The column $m=1$ in Table 3 shows [1, A000125] according to (2).

TABLE 3. The number $A_{n, m, 3}$ of $n \times m$ binary matrices with at most three 1's in each row or column.

$A_{n, n,\lfloor n / 2\rfloor}$ are in [1, A247158]. The hyperdiagonal $A_{n, n, n-1}$ yields [1, A048291], which means if a $n \times n$ matrix has at most $n-11$ 's, there is at least one zero in each row or column, and flipping the elements of the matrices counts also the matrices with at least one 1 and therefore no fully blanked zero.

## Appendix A. Maple Implementation

        # recousre to A(n-1,m,k,freqprime)
        # add R=0: 1 way A(n-1,m,k,[c0,c1,c2..,ck-1]) >> A(n,m,k,[c0,c1,\ldotsck-1])
        # add R=1: add 1 to c0' in binomial(c0',1) ways or add 1 to c1' in binomial(c1',1) ways
        # C(c0,1)*A(n-1,m,k,[c0, c1,\ldots,ck-1]) + C (c1,1)*A(n-1,m,k,[c0, c1, ...ck-1])+...
        # add R=2: add 2 to c0' in binomial(c0',2) ways or add 2 to c1' in binomial(c1',2) ways
        # or A(n,m,k,[c0,c1+2,\ldots.]
        # or mixed add 1 to c0' and 1 to c1' in binomial(c0',1)*binomial(c1',1)*A(n-1,m,k,[c0,c
        # A(n,m,k,[c0+1,c1+1,..]
```

$\# \mathrm{C}(\mathrm{c} 0,1) * \mathrm{~A}(\mathrm{n}-1, \mathrm{~m}, \mathrm{k},[\mathrm{c} 0, \mathrm{c} 1, \ldots, \mathrm{ck}-1])+\mathrm{C}(\mathrm{c} 1,1) * \mathrm{~A}(\mathrm{n}-1, \mathrm{~m}, \mathrm{k},[\mathrm{c} 0, \mathrm{c} 1, \ldots \mathrm{ck}-1])+\ldots$
$\# \mathrm{~N}$ is the number of 1 's in row n in the range $0<=\mathrm{N}<=\mathrm{k}$. for N from 0 to $k$ do
\# That number of 1's can be split into gr[1] added to the columns with \# no ones yet, into gr[2] added to the columns with 1 ones yet,..
\# added to the columns with k-1 ones yet. There cannot be 1's added to
\# columns that already havy $k$ ones, so this splitting of N is only
\# into k groups, the last argument to nonnCompo.
for gr in nonnCompo( $\mathrm{N}, \mathrm{k}$ ) do
\# last argument is not $k+1$, because we cannot add to freq[-1]
\# The frequencies F[] of the previous matrix with $\mathrm{n}-1$ rows undergo the \# $\mathrm{F}[0] \rightarrow \mathrm{F}[0]-\mathrm{gr}[0], \mathrm{F}[1] \rightarrow \mathrm{F}[1]+\mathrm{gr}[0]-\mathrm{gr}[1], \ldots \mathrm{F}[\mathrm{k}-1]->\mathrm{F}[\mathrm{k}-1]+\mathrm{gr}[\mathrm{k}-2$
\# $\mathrm{F}[\mathrm{k}]$-> $\mathrm{F}[\mathrm{k}]+\mathrm{gr}[\mathrm{k}-1]$.
\# Valid transitions demand that of course the $\mathrm{F}[\mathrm{i}]$ are $>=0$, but
\# (not to be overlooked) that all $\mathrm{F}[\mathrm{i}]-\mathrm{gr}[\mathrm{i}]$ are also $>=0,0<=\mathrm{i}<\mathrm{k}$.
\# Now Maple indices are all 1 up:
\# $\mathrm{F}[1]->\mathrm{F}[1]-\mathrm{gr}[1], \mathrm{F}[2] \rightarrow \mathrm{F}[2]+\mathrm{gr}[1]-\mathrm{gr}[2], \ldots \mathrm{F}[\mathrm{k}]->\mathrm{F}[\mathrm{k}]+\mathrm{gr}[\mathrm{k}-1]-\mathrm{gr}$
\# $F[k+1]$ $\rightarrow F[k+1]+g r[k]$ and all $F[i]-g r[i]>=0,1<=i<=k$.
\# And the frequencies $f[]$ with the matrix of $n$ rows
\# are by solving to the right hand sides. $f[1]=F[1]-g r[1], f[i]=F[i]-g r$
\# and $f[k+1]=F[k+1]+g r[k]$.
\# $f[1]+\operatorname{gr}[1] \rightarrow f[1] . f[2]+g r[2]-g r[1] ~ \rightarrow f[2] \ldots f[k]+g r[k]-g r[k-1]->$
\# $\mathrm{f}[\mathrm{k}+1]-\mathrm{gr}[\mathrm{k}] \rightarrow \mathrm{f}[\mathrm{k}+1]$.
